

# Secure Your Email Access On Mobile Devices

The ActiveSync technology used in Exchange servers allows mobile devices to connect to corporate email systems using a username and password. However, if the username and password are compromised, these credentials can easily be added to mobile devices, granting unauthorized access to corporate email accounts. To prevent this security vulnerability, the D2M (Device to Mail) solution allows users to authenticate their mobile devices using multi-factor authentication.

With D2M, users can manage their mobile devices through a web-based portal. After securely logging into the system, users can view, approve, block, or completely wipe their connected devices. This ensures that only authenticated devices can access the corporate email system, preventing unauthorized access.

# Ensure Complete Security For Corporate Email Access With 2FA Via D2M!

D2M solution enables effective implementation of mobile device management and security policies. This strengthens corporate information security and fully secures email access from mobile devices. Without 2FA (Two-Factor Authentication) for corporate email access, it is impossible to fully protect your data!

Since the Exchange Server ActiveSync protocol does not support any MFA solution provided by Microsoft, even if multi-factor authentication (MFA) is applied at other endpoints, the system cannot be fully secured if the ActiveSync protocol remains exposed. The D2M solution offers a strong authentication mechanism for mobile devices and enables end users to securely provision their own devices. It establishes a process that ensures users can only access their emails through approved devices over the ActiveSync protocol.

This prevents unauthorized access to corporate data through unapproved devices in the event of a compromised username and password. .
